PLOTTING FAILURES PER MACHINE
IN SERVICE FOR SYSTEMS OBEYING
THE ULTIMATE VALUE LAW

#### INTRODUCTION

Whenever we are concerned with a complex system, which can fail in a multitude of different modes, it turns out that the distribution function for times to failure is not a simple straight line on Weibull probability As a matter of fact, the Weibull plot starts out with a low slope at the early stages and ends up with a steep slope at the upper stages. This is true even for debugged systems. From experience with complex systems it has been found that such systems have a MAXIMUM LIFE ( i.e., an ULTIMATE VALUE for hours of endurance) . It is this existence of a maximum life (ultimate value) which causes the Weibull plot to steepen at higher percentiles of the life distribution. For this reason it makes more sense to use the ULTIMATE VALUE MATHEMATICAL FUNCTION in analyzing The purpose of this bulletin is to describe a certain complex systems. method of plotting failures per machine from field data by employing the ULTIMATE VALUE MATHEMATICAL THEORY. In this way we can fit straight lines to data on failures per machine for machines which obey the ULTIMATE VALUE Such systems would not yield straight lines for LOG-LOG Plots of LAW. failures per machine.

Vol. 7, Bul. 5

### BASIC MATHEMATICAL MODEL

The ULTIMATE VALUE CUMULATIVE DISTRIBUTION FUNCTION for first failures

of a system has the following form:

$$F(X) = EXP \left[1 - \left(\frac{U}{X}\right)^{\sqrt{3}}\right]$$
 (1)

where

X = Hours of Service (or other time units)

U = Ultimate Value ( Maximum Life)

Shape Parameter (Slope of Plot on Ultimate Value Paper)

F(X) = Fraction of Machines in the Population which have failed at least once in X hours.

In order to come up with a mathematical formula for FAILURES PER MACHINE in X hours, we must derive a formula for ENTROPY from equation (1).

ENTROPY at time X is defined as the value of  $\frac{1}{1 - F(X)}$ 

If we denote ENTROPY by the symbol &, then

$$\mathcal{E} = \ln \frac{1}{1 - F(X)}$$

Vol. 7 Bul. 5

Thus, (1) can be written as
$$1 - EXP(-C) = EXP \left[1 - \left(\frac{U}{X}\right)^{2}\right] \qquad (2)$$

Taking the logarithm of both sides of (2):

In (1 - EXP(-
$$\xi$$
)) = 1 -  $\left(\frac{\overline{u}}{\overline{x}}\right)^{\sqrt{2}}$ 

Transposing:
$$1 - \ln(1 - EXP(-\xi)) = \left(\frac{\overline{u}}{\overline{x}}\right)^{\sqrt{2}}$$

Inverting:
$$\frac{1}{1 - \ln(1 - EXP(-\xi))} = \left(\frac{\overline{x}}{\overline{u}}\right)^{\sqrt{2}}$$
(3)

Taking the logarithm of both sides of (3):

$$\ln \left[ \frac{1}{1 - \ln(1 - EXP(-\xi))} \right] = \sqrt{\ln x - \sqrt{\ln u}}$$

Equation (4) is a LINEAR RELATION between 
$$\ln X$$
 and  $\ln \left[\frac{1}{1 - \ln(1 - \exp(-\xi))}\right]$ .

where

X = Time in Service

= Failures Per Machine

## CONSTRUCTION OF SYSTEMS PLOTTING PAPER

From equation (4) we can construct a plotting grid which will give straight lines for the data on failures per machine in a complex machine (system) obeying the ultimate value law. This is done by making the abscissa scale a LOG scale (for LN X), and by making the prdinate scale  $\ln \left[\frac{1}{1-\ln(1-\text{EXP}(-\mathcal{E}))}\right], \text{ where the ENTROPY } \mathcal{E} \text{ is equivalent}$ to the failures per machine in service time X. The logarithmic abscissa scale presents no difficulty. However, the ORDINATE SCALE must be calibrated in accordance with the following table:

| FAILURES PER MACHINE | VALUE OF THE TRANSFORMED ORDINATE  In 1 - In(1 - EXP(-C)) |
|----------------------|---|
| .00001               | - 2.52676   |
| .00002               | - 2.469775  |
| .00003               | - 2.434862  |

IN SERVICE

TIME

Vol. 7, Bul. 5

### A NUMERICAL EXAMPLE

We are given a set of failure data on a certain collection of machines out in the field. These machines have seen different hours of service (ages 110 hrs. to 760 hrs.). The number of failures for machines of these different ages are listed in column (3), while the ages are listed in column (1), and the number of machines of each age appear in column (2) of the data table belows

|     |              |     | DATA TAB | TE_           |       |    |        |               |       |

|     |              |     |          |               |       |    |        |               |       |

### ANALYSIS AND GRAPHICAL PLOTTING

From the DATA TABLE in the preceding section we divide each number in column (3) by the corresponding number in column (2) to obtain the FAILURES PER MACHINE corresponding to each age in column (1), as follows:

|      |                 | FAILURES | PER | MACHINE | The second secon |      | d- 8           |
|------|-----------------|----------|-----|---------|--|------|----------------|
| AGE  | (1)<br>IN HOURS |          |     | F       | (3)<br>AILURES   | PER  | (2)<br>MACHINE |
| 1    | 110             |          |     |         |  | .100 |                |
|      | 160             |          |     |         |  | 222  |                |
|      | 220             |          |     |         | 4  | 357  |                |
|      | 285             |          |     |         |  | .500 |                |
|      | 355             |          |     |         |  | .684 |                |
|      | 440             |          |     |         |  | .914 |                |
| - 14 | 530             |          |     |         |  | .200 |                |
|      | 640             |          |     |         | 1  | .600 |                |
|      | 760             |          |     |         | 2  | .312 |                |

We now plot AGE IN HOURS as ABSCISSA and FAILURES PER MACHINE as ORDINATE
on our SYSTEM ENTROPY GRID to obtain FIGURE 1, which has a SLOPE PARAMETER of

\*
.56 and an ULTIMATE VALUE of 913 hours.

<sup>\*</sup> NOTE: The SLOPE in FIGURE 1 is measured to be 1.68, i.e., THREE TIMES the TRUE SLOPE PARAMETER .56 .
